SOCIAL & ECOLOGICAL DYNAMICS IN CENTRAL MONGOLIA

TUV | AIMAG & SOUM LEVEL

Utilizing geospatial and social survey data towards a greater understanding of land cover and land use change (LCLUC), labor, and migration within Mongolia's Provinces of Tuv.

PURPOSE OF REPORT

Mongolia, at the heart of Central Asia, is home to one of the largest remaining grassland ecosystems in the world. Grassland comprises 73% of Mongolia, which supports over 67.1 million head of livestock and almost 181,000 herding families. However, rapid social and demographic shifts in rural communities, in combination with a changing climate, pose risks to both sustainable management of herding and grassland resources. Very little is known about how rural out-migration in Mongolia is changing the demographics of rural households, the availability of herding labor, or the subsequent impacts on grassland conditions.

This report showcases the results of a land use and land cover study spanning a period of 6 years within the Mongolian provinces of Tuv. It was made possible through collaboration between key stakeholders within the Mongolian government, the Zoological Society of Luujin, and researchers at Cornell University and the Smithsonian Conservation Biology Society, and displays the results of a mixed methods study involving geospatial analyses and the interpretation of a social survey involving 188 nomadic herding families within the region.

Additional information and context outside of this report can be viewed here.

(<https://github.com/RCBlackburn/StEPPES>)

ACKNOWLEDGEMENTS

This report would not have been possible without the funding and support of the National Aeronautics and Space Administration's Land Cover Land Use Change Grant (No. 80NSSC22K0468), and collaboration between researchers at the Luujin Zoological Society, The Smithsonian Institute, and the Department of Natural Resources and the Environment at Cornell University.

Additionally, we thank the following individuals for their assistance with data collection, logistics, and insights they shared with our research team: Mikel Alvis, Michael Meneshian Oyundelger Enkhtuvshin, and particularly the staff at Luujin Zoological Society, including: Tuvshin Nergui, Odonchirmeg Sukhbaatar, Munkhzaya Myagmarjav, Batbayar Banzragch, Bolor Radnaabazar and Bilguun Batkhuyag.

Finally, we thank the 188 nomadic herding families and the generous gift of their time in assisting our researchers and field technicians in the completion of social surveys which have provided great insight in the creation of this report.

STATE OF THE STEPPE 2025 - AIMAG LEVEL

TUV

BACKGROUND |

Tuv Aimag is situated centrally within Mongolia. It encloses the city limits of the capital Ulaanbaatar, but is separately administered. It is comprised of semi-arid rolling steppe and mountainous terrain in the central province. Tuv has a population of 94,462. The aimag is especially noted for its animal husbandry and livestock products such as cashmere.

ISSUES |

A changing climate in Tuv has increased both the frequency and severity of extreme climate events such as drought and dzud. This poses a threat to livestock-based livelihoods throughout the region, as herders are more likely to lose livestock in these events. Herders typically respond to such losses by increasing the number of their herd to act as a buffer. This in turn worsens grassland conditions, as larger herds' reliance on the same area of grassland leads to overgrazing and degradation of grassland ecosystems throughout Tuv. Many families, facing economic hardship, are abandoning herding altogether and migrating into larger cities such as Ulaanbaatar to seek non-herding employment. This phenomenon of rural outmigration, while contributing to population growth within cities, is also affecting the ability of remaining rural herders to carry out tasks related to livestock management, herding, and general household labor.

INSIGHTS |

Analysis of vegetation height, cover, and overall volume throughout Tuv aimag revealed that vegetation loss and gain appear to be spatially clustered, however, the average amount of vegetation has remained stable over the last six years. While there was a noticeable dip in all vegetation characteristics in 2020, average vegetation conditions have returned across the aimag.

Survey respondents reported a number of interesting findings (pg. 10 of this report). A large majority of respondents reported moderate to significant degradation of both availability and condition of existing grazing lands. This may be a factor in many respondents' decision to shift their herding management practices in the next five years. Herders generally indicated that rural outmigration of family members has not affected their herding practices nor the availability of labor. Despite this, herders within Tuv report lower mobility in recent years than in the past, moving fewer times per year as well as shorter distances when they do move.

SOLUTIONS |

Changes in volume of forage may be driven by changes in composition of pasture vegetation, including shifts toward less palatable species. Local monitoring within each soum could target vegetation change hotspots to assess vegetation composition to better understand actual forage quality. In addition, coordination of otor movements could target zones with increasing vegetation volume. We also recommend that regional administrators begin tracking the location and total area of fenced pasture, as this may impact mobility and localized vegetation conditions.

STATE OF THE STEPPE 2025 - AIMAG LEVEL

TUV

METHODS & CONTEXT

VEGETATION MAP CREATION |

Vegetation maps were created between 2019-2024 through a two-step scaling approach using field observations, unoccupied aerial vehicles (UAVs), and Sentinel-2 imagery. Each pixel of the vegetation cover, height, and volume maps represents the average vegetation value of that characteristic over a 20 x 20 meter area. Our data collection was within the Mongolian-Manchurian grassland ecoregion defined by the World Wildlife Fund (the red in the map to the right) in 2023, but we provide predictions across the entire province. While we are confident in our maps' value in most of the surrounding steppe eco-types, data from forested areas are not accurate. More information on the mapping project can be found at the StEPES project repository provided in the table of contents.

TUV INTERPRETATIONS |

Maps for change in vegetation cover (%), vegetation height (cm) and vegetation volume (m^3) between 2019-2024 are provided below. Change is defined for each pixel as the average annual rate of change by estimating the slope of a linear model for each vegetation characteristic value and year. This can be interpreted as the average amount of increasing (blue) or decreasing (red) vegetation seen within the study period.

TUV VEGETATION TREND FIGURES |

The average values for vegetation cover (a), vegetation height (b), vegetation volume (c) are provided for each year in the plot following the map. The trend of these values is displayed as a dashed grey line, and the error bars around the mean represent one standard deviation.

TUV HOUSEHOLD SURVEY TABLE |

We also provide seven questions reported during the household survey data collected in the winter of 2023. These data were taken from households within four soums: Bayan, Bayantsagaan, Buren, and Delgerkhaan.

STATE OF THE STEPPE 2025 - SOUM LEVEL

METHODS & CONTEXT

TUV SOUM MAP INTERPRETATIONS |

Maps for change in vegetation cover (%), vegetation height (cm) and vegetation volume (m^3) between 2019-2024 are provided below. Change is defined for each pixel as the average annual rate of change by estimating the slope of a linear model for each vegetation characteristic value and year. This can be interpreted as the average amount of increasing (blue) or decreasing (red) vegetation seen within the study period.

TUV SOUM VEGETATION TREND FIGURES |

The average values for each soum for vegetation cover (a), vegetation height (b), and vegetation volume (c) are provided for each year in the plots following the maps. The trend of these values is displayed as a dashed grey line.

Tuv soum Map | The extent of each soum that falls within the Mongolian-Manchurian grassland ecoregion defined by the World Wildlife Fund is in red.
